Veriopt

July 3, 2021

Abstract

The Veriopt project aims to prove the optimization pass of the GraalVM compiler. The GraalVM compiler includes a sophisticated Intermediate Representation (IR) in the form of a sea-of-nodes based graph structure. We first define the IR graph structure in the Isabelle/HOL interactive theorem prover. We subsequently give the evaluation of the structure a semantics based on the current understanding of the purpose of each IR graph node. Optimization phases are then encoded including the static analysis passes required for an optimization. Each optimization phase is proved to be correct by proving that a bisimulation exists between the unoptimized and optimized graphs. The following document has been automatically generated from the Isabelle/HOL source to provide a very comprehensive definition of the semantics and optimizations introduced by the Veriopt project.

Contents

1 Runtime Values and Arithmetic **3**

2 Nodes **8**
2.1 Types of Nodes 8
2.2 Hierarchy of Nodes 15

3 Stamp Typing **21**

4 Graph Representation **25**
4.0.1 Example Graphs 28

5 Data-flow Semantics **29**
5.1 Data-flow Tree Representation 30
5.2 Data-flow Tree Evaluation 39
5.3 Data-flow Tree Refinement 40

6 Data-flow Expression-Tree Theorems **41**
6.1 Extraction and Evaluation of Expression Trees is Deterministic. 41
6.2 Example Data-flow Optimisations 45
6.3 Monotonicity of Expression Optimization 45

7 Control-flow Semantics **46**
7.1 Heap 46
7.2 Intraprocedural Semantics 47
7.3 Interprocedural Semantics 49
7.4 Big-step Execution 50
7.4.1 Heap Testing 51

begin

In order to properly implement the IR semantics we first introduce a new type of runtime values. Our evaluation semantics are defined in terms of these runtime values. These runtime values represent the full range of primitive types currently allowed by our semantics, ranging from basic integer types to object references and eventually arrays.

An object reference is an option type where the None object reference points to the static fields. This is examined more closely in our definition of the heap.

Java supports 64, 32, 16, 8 signed ints, plus 1 bit (boolean) ints. Our Value type models this by keeping the value as an infinite precision signed int, but also carrying along the number of bits allowed.

So each (IntVal b v) should satisfy the invariants:

$b \in \{1::'a, 8::'a, 16::'a, 32::'a, 64::'a\}$

$1 < b \Longrightarrow v \equiv scast\ (signed\text{-}take\text{-}bit\ b\ v)$

type-synonym *int64* = *64 word* — long
type-synonym *int32* = *32 word* — int
type-synonym *int16* = *16 word* — short
type-synonym *int8* = *8 word* — char
type-synonym *int1* = *1 word* — boolean

type-synonym *objref* = *nat option*

datatype *Value* =
UndefVal |
IntVal32 int32 |
IntVal64 int64 |
FloatVal float |
ObjRef objref |
ObjStr string

We define integer values to be well-formed when their bit size is valid and their integer value is able to fit within the bit size. This is defined using the *wf-value* function.

— Check that a signed int value does not overflow b bits.
fun *fits-into-n* :: *nat* ⇒ *int* ⇒ *bool* **where**
fits-into-n b val = ((−(*2*^(*b*−*1*)) ≤ *val*) ∧ (*val* < (*2*^(*b*−*1*))))

```
fun wf-bool :: Value ⇒ bool where
  wf-bool (IntVal32 v) = (v = 0 ∨ v = 1) |
  wf-bool - = False

fun val-to-bool :: Value ⇒ bool where
  val-to-bool (IntVal32 v) = (v = 1) |
  val-to-bool - = False

fun bool-to-val :: bool ⇒ Value where
  bool-to-val True = (IntVal32 1) |
  bool-to-val False = (IntVal32 0)

value sint(word-of-int (1) :: int1)
```

We need to introduce arithmetic operations which agree with the JVM.

Within the JVM, bytecode arithmetic operations are performed on 32 or 64 bit integers, unboxing where appropriate.

The following collection of intval functions correspond to the JVM arithmetic operations.

```
fun intval-add32 :: Value ⇒ Value ⇒ Value where
  intval-add32 (IntVal32 v1) (IntVal32 v2) = (IntVal32 (v1+v2)) |
  intval-add32 - - = UndefVal

2 Nodes

2.1 Types of Nodes

theory *IRNodes2*
imports
Values2
begin

The GraalVM IR is represented using a graph data structure. Here we define the nodes that are contained within the graph. Each node represents a Node subclass in the GraalVM compiler, the node classes have annotated fields to indicate input and successor edges.

We represent these classes with each IRNode constructor explicitly labelling a reference to the node IDs that it stores as inputs and successors.

The inputs_of and successors_of functions partition those labelled references into input edges and successor edges of a node.

To identify each Node, we use a simple natural number index. Zero is always the start node in a graph. For human readability, within nodes we write INPUT (or special case thereof) instead of ID for input edges, and SUCC instead of ID for control-flow successor edges. Optional edges are handled as "INPUT option" etc.

2.2 Hierarchy of Nodes

theory *IRNodeHierarchy*
imports *IRNodes2*
begin

It is helpful to introduce a node hierarchy into our formalization. Often the GraalVM compiler relies on explicit type checks to determine which operations to perform on a given node, we try to mimic the same functionality by using a suite of predicate functions over the IRNode class to determine inheritance.

As one would expect, the function is<ClassName>Type will be true if the node parameter is a subclass of the ClassName within the GraalVM compiler.

These functions have been automatically generated from the compiler.

fun *is-EndNode* :: *IRNode* ⇒ *bool* **where**
is-EndNode EndNode = *True* |

3 Stamp Typing

theory *Stamp2*
imports *Values2*
begin

The GraalVM compiler uses the Stamp class to store range and type information for a given node in the IR graph. We model the Stamp class as a datatype, Stamp, and provide a number of functions on the datatype which correspond to the class methods within the compiler.

Stamp information is used in a variety of ways in optimizations, and so, we additionally provide a number of lemmas which help to prove future optimizations.

datatype *Stamp* =

```
  VoidStamp
  | IntegerStamp (stp-bits: nat) (stpi-lower: int) (stpi-upper: int)

  | KlassPointerStamp (stp-nonNull: bool) (stp-alwaysNull: bool)

definition *start-end-graph*:: *IRGraph* **where**
start-end-graph = *irgraph* [(*0*, *StartNode None 1*, *VoidStamp*), (*1*, *ReturnNode None None*, *VoidStamp*)]

Example 2: public static int sq(int x) return x * x;
[1 P(0)] / [0 Start] [4 *] | / V / [5 Return]

definition *eg2-sq* :: *IRGraph* **where**
eg2-sq = *irgraph* [
(*0*, *StartNode None 5*, *VoidStamp*),
(*1*, *ParameterNode 0*, *default-stamp*),
(*4*, *MulNode 1 1*, *default-stamp*),
(*5*, *ReturnNode* (*Some 4*) *None*, *default-stamp*)

]

value *input-edges eg2-sq*
value *usages eg2-sq 1*

end

5 Data-flow Semantics

theory *IRTreeEval*
imports
Graph.IRGraph
begin

We define a tree representation of data-flow nodes, as an abstraction of the graph view.

Data-flow trees are evaluated in the context of a method state (currently called MapState in the theories for historical reasons).

The method state consists of the values for each method parameter, references to method parameters use an index of the parameter within the parameter list, as such we store a list of parameter values which are looked up at parameter references.

The method state also stores a mapping of node ids to values. The contents of this mapping is calculates during the traversal of the control flow graph.

As a concrete example, as the *SignedDivNode* can have side-effects (during division by zero), it is treated as part of the control-flow, since the data-flow phase is specified to be side-effect free. As a result, the control-flow semantics for *SignedDivNode* calculates the value of a node and maps the node identifier to the value within the method state. The data-flow semantics then just reads the value stored in the method state for the node.

5.3 Data-flow Tree Refinement

We define the induced semantic equivalence relation between expressions. Note that syntactic equality implies semantic equivalence, but not vice versa.

definition *equiv-exprs* :: *IRExpr* ⇒ *IRExpr* ⇒ *bool* (- ≐ - *55*) **where**
(*e1* ≐ *e2*) = (∀ *m p v*. (([*m*,*p*] ⊢ *e1* ↦ *v*) ⟷ ([*m*,*p*] ⊢ *e2* ↦ *v*)))

We also prove that this is a total equivalence relation (*equivp equiv-exprs*) (HOL.Equiv_Relations), so that we can reuse standard results about equivalence relations.

lemma *equivp equiv-exprs*
⟨*proof*⟩

We define a refinement ordering over IRExpr and show that it is a preorder. Note that it is asymmetric because e2 may refer to fewer variables than e1.

instantiation *IRExpr* :: *preorder* **begin**

definition
le-expr-def [*simp*]: (*e1* ≤ *e2*) ⟷ (∀ *m p v*. (([*m*,*p*] ⊢ *e1* ↦ *v*) ⟶ ([*m*,*p*] ⊢ *e2* ↦ *v*)))

(*BinaryExpr BinSub*
(*LeafExpr y* (*IntegerStamp 32 loy hiy*))
(*LeafExpr x* (*IntegerStamp 32 lox hix*))))
≤ (*LeafExpr y* (*IntegerStamp 32 loy hiy*))
⟨*proof*⟩

6.3 Monotonicity of Expression Optimization

We prove that each subexpression position is monotonic. That is, optimizing a subexpression anywhere deep inside a top-level expression also optimizes

that top-level expression.

Note that we might also be able to do this via reusing Isabelle's 'mono' operator (HOL.Orderings theory), proving instantiations like 'mono (UnaryExpr op)', but it is not obvious how to do this for both arguments of the binary expressions.

lemma *mono-unary*:
  assumes $e \leq e'$
  shows $(UnaryExpr\ op\ e) \leq (UnaryExpr\ op\ e')$
  ⟨*proof*⟩

lemma *mono-binary*:
  assumes $x \leq x'$
  assumes $y \leq y'$
  shows $(BinaryExpr\ op\ x\ y) \leq (BinaryExpr\ op\ x'\ y')$
  ⟨*proof*⟩

lemma *mono-conditional*:
  assumes $ce \leq ce'$
  assumes $te \leq te'$
  assumes $fe \leq fe'$
  shows $(ConditionalExpr\ ce\ te\ fe) \leq (ConditionalExpr\ ce'\ te'\ fe')$
⟨*proof*⟩

end

7 Control-flow Semantics

theory *IRStepObj*
  imports
    IRTreeEval
begin

7.1 Heap

The heap model we introduce maps field references to object instances to runtime values. We use the H[f][p] heap representation. See *cite*{*heap−reps−2011*}.

We also introduce the DynamicHeap type which allocates new object references sequentially storing the next free object reference as 'Free'.

type-synonym $('a, 'b)\ Heap = 'a \Rightarrow 'b \Rightarrow Value$
type-synonym $Free = nat$
type-synonym $('a, 'b)\ DynamicHeap = ('a, 'b)\ Heap \times Free$

fun *h-load-field* :: *'a* ⇒ *'b* ⇒ (*'a*, *'b*) *DynamicHeap* ⇒ *Value* **where**
h-load-field f r (*h*, *n*) = *h f r*
