Veriopt

December 16, 2022

Abstract

The Veriopt project aims to prove the optimization pass of the GraalVM compiler. The GraalVM compiler includes a sophisticated Intermediate Representation (IR) in the form of a sea-of-nodes based graph structure. We first define the IR graph structure in the Isabelle/HOL interactive theorem prover. We subsequently give the evaluation of the structure a semantics based on the current understanding of the purpose of each IR graph node. Optimization phases are then encoded including the static analysis passes required for an optimization. Each optimization phase is proved to be correct by proving that a bisimulation exists between the unoptimized and optimized graphs. The following document has been automatically generated from the Isabelle/HOL source to provide a very comprehensive definition of the semantics and optimizations introduced by the Veriopt project.

Contents

1 Operator Semantics

theory *Values*
  imports
    HOL−Library.Word
    HOL−Library.Signed-Division
    HOL−Library.Float
    HOL−Library.LaTeXsugar
begin

In order to properly implement the IR semantics we first introduce a type that represents runtime values. These runtime values represent the full range of primitive types currently allowed by our semantics, ranging from basic integer types to object references and arrays.

Note that Java supports 64, 32, 16, 8 signed ints, plus 1 bit (boolean) ints, and char is 16-bit unsigned. E.g. an 8-bit stamp has a default range of -128..+127. And a 1-bit stamp has a default range of -1..0, surprisingly.

During calculations the smaller sizes are sign-extended to 32 bits, but explicit widening nodes will do that, so most binary calculations should see equal input sizes.

An object reference is an option type where the *None* object reference points to the static fields. This is examined more closely in our definition of the heap.

type-synonym *int64* = *64 word* — long
type-synonym *int32* = *32 word* — int
type-synonym *int16* = *16 word* — short
type-synonym *int8* = *8 word* — char
type-synonym *int1* = *1 word* — boolean

abbreviation *valid-int-widths* :: *nat set* **where**
  valid-int-widths ≡ {*1*, *8*, *16*, *32*, *64*}

experiment begin

Option 2: explicit width stored with each integer value. However, this does not help us to distinguish between short (signed) and char (unsigned).

typedef *IntWidth* = { *w* :: *nat* . *w=1* ∨ *w=8* ∨ *w=16* ∨ *w=32* ∨ *w=64* }
  by *blast*

setup-lifting *type-definition-IntWidth*

lift-definition *IntWidthBits* :: *IntWidth* ⇒ *nat*

1.1 Arithmetic Operators

We need to introduce arithmetic operations which agree with the JVM.

Within the JVM, bytecode arithmetic operations are performed on 32 or 64 bit integers, unboxing where appropriate.

The following collection of intval functions correspond to the JVM arithmetic operations. We merge the 32 and 64 bit operations into a single function, even though the stamp of each IRNode tells us exactly what the bit widths will be. These merged functions make it easier to do the instantiation of Value as 'plus', etc. It might be worse for reasoning, because it could cause more case analysis, but this does not seem to be a problem in practice.

fun *intval-add* :: *Value* ⇒ *Value* ⇒ *Value* **where**
  intval-add (*IntVal b1 v1*) (*IntVal b2 v2*) =
    (*if b1* = *b2 then IntVal b1* (*take-bit b1* (*v1*+*v2*)) *else UndefVal*) |
  intval-add - - = *UndefVal*

fun *intval-sub* :: *Value* ⇒ *Value* ⇒ *Value* **where**

intval-conditional cond tv fv = (*if* (*val-to-bool cond*) *then tv else fv*)

1.4 Narrowing and Widening Operators

Note: we allow these operators to have inBits=outBits, because the Graal compiler also seems to allow that case, even though it should rarely / never arise in practice.

value *sint*(*signed-take-bit 0* (*1* :: *int32*))

fun *intval-narrow* :: *nat* ⇒ *nat* ⇒ *Value* ⇒ *Value* **where**
intval-narrow inBits outBits (*IntVal b v*) =
(*if inBits* = *b* ∧ *0* < *outBits* ∧ *outBits* ≤ *inBits* ∧ *inBits* ≤ *64*
then new-int outBits v
else UndefVal) |
intval-narrow - - - = *UndefVal*

value *sint* (*signed-take-bit 7* ((*256* + *128*) :: *int64*))

fun *intval-sign-extend* :: *nat* ⇒ *nat* ⇒ *Value* ⇒ *Value* **where**
intval-sign-extend inBits outBits (*IntVal b v*) =
(*if inBits* = *b* ∧ *0* < *inBits* ∧ *inBits* ≤ *outBits* ∧ *outBits* ≤ *64*
then new-int outBits (*signed-take-bit* (*inBits* − *1*) *v*)
else UndefVal) |
intval-sign-extend - - - = *UndefVal*

fun *intval-zero-extend* :: *nat* ⇒ *nat* ⇒ *Value* ⇒ *Value* **where**
intval-zero-extend inBits outBits (*IntVal b v*) =
(*if inBits* = *b* ∧ *0* < *inBits* ∧ *inBits* ≤ *outBits* ∧ *outBits* ≤ *64*
then new-int outBits (*take-bit inBits v*)
else UndefVal) |
intval-zero-extend - - - = *UndefVal*

Some well-formedness results to help reasoning about narrowing and widening operators

lemma *intval-narrow-ok*:
assumes *intval-narrow inBits outBits val* ≠ *UndefVal*
shows *0* < *outBits* ∧ *outBits* ≤ *inBits* ∧ *inBits* ≤ *64* ∧ *outBits* ≤ *64* ∧
is-IntVal val ∧
intval-bits val = *inBits*
using *assms intval-narrow.simps neq0-conv intval-bits.simps*
by (*metis Value.disc*(*2*) *intval-narrow.elims le-trans*)

lemma *intval-sign-extend-ok*:
assumes *intval-sign-extend inBits outBits val* ≠ *UndefVal*
shows *0* < *inBits* ∧
inBits ≤ *outBits* ∧ *outBits* ≤ *64* ∧

is-IntVal val ∧
intval-bits val = inBits
using *assms intval-sign-extend.simps neq0-conv*
by (*metis intval-bits.simps intval-sign-extend.elims is-IntVal-def*)

lemma *intval-zero-extend-ok*:
assumes *intval-zero-extend inBits outBits val ≠ UndefVal*
shows *0 < inBits* ∧
inBits ≤ outBits ∧ *outBits ≤ 64* ∧
is-IntVal val ∧
intval-bits val = inBits
using *assms intval-sign-extend.simps neq0-conv*
by (*metis intval-bits.simps intval-zero-extend.elims is-IntVal-def*)

1.5 Bit-Shifting Operators

definition *shiftl* (**infix** *<<* *75*) **where**
shiftl w n = (*push-bit n*) *w*

lemma *shiftl-power*[*simp*]: (*x*::(*'a*::*len*) *word*) * (*2* ^ *j*) = *x* << *j*
unfolding *shiftl-def* **apply** (*induction j*)
apply *simp* **unfolding** *funpow-Suc-right*
by (*metis* (*no-types*, *opaque-lifting*) *push-bit-eq-mult*)

lemma (*x*::(*'a*::*len*) *word*) * ((*2* ^ *j*) + *1*) = *x* << *j* + *x*
by (*simp add*: *distrib-left*)

lemma (*x*::(*'a*::*len*) *word*) * ((*2* ^ *j*) − *1*) = *x* << *j* − *x*
by (*simp add*: *right-diff-distrib*)

lemma (*x*::(*'a*::*len*) *word*) * ((*2*^*j*) + (*2*^*k*)) = *x* << *j* + *x* << *k*
by (*simp add*: *distrib-left*)

lemma (*x*::(*'a*::*len*) *word*) * ((*2*^*j*) − (*2*^*k*)) = *x* << *j* − *x* << *k*
by (*simp add*: *right-diff-distrib*)

definition *shiftr* (**infix** *>>>* *75*) **where**
shiftr w n = (*drop-bit n*) *w*

value (*255* :: *8 word*) >>> (*2* :: *nat*)

definition *sshiftr* :: *'a* :: *len word* ⇒ *nat* ⇒ *'a* :: *len word* (**infix** *>>* *75*) **where**
sshiftr w n = *word-of-int* ((*sint w*) *div* (*2* ^ *n*))

value (*128* :: *8 word*) >> *2*

Note that Java shift operators use unary numeric promotion, unlike other binary operators, which use binary numeric promotion (see the Java lan-

guage reference manual). This means that the left-hand input determines the output size, while the right-hand input can be any size.

fun *shift-amount* :: *iwidth* ⇒ *int64* ⇒ *nat* **where**
shift-amount b val = *unat* (*and val* (*if b* = *64 then 0x3F else 0x1f*))

fun *intval-left-shift* :: *Value* ⇒ *Value* ⇒ *Value* **where**
intval-left-shift (*IntVal b1 v1*) (*IntVal b2 v2*) = *new-int b1* (*v1* << *shift-amount b1 v2*) |
intval-left-shift - - = *UndefVal*

Signed shift is more complex, because we sometimes have to insert 1 bits at the correct point, which is at b1 bits.

fun *intval-right-shift* :: *Value* ⇒ *Value* ⇒ *Value* **where**
intval-right-shift (*IntVal b1 v1*) (*IntVal b2 v2*) =
(*let shift* = *shift-amount b1 v2 in*
let ones = *and* (*mask b1*) (*not* (*mask* (*b1* − *shift*) :: *int64*)) *in*
(*if int-signed-value b1 v1* < *0*
then new-int b1 (*or ones* (*v1* >>> *shift*))
else new-int b1 (*v1* >>> *shift*))) |
intval-right-shift - - = *UndefVal*

fun *intval-uright-shift* :: *Value* ⇒ *Value* ⇒ *Value* **where**
intval-uright-shift (*IntVal b1 v1*) (*IntVal b2 v2*) = *new-int b1* (*v1* >>> *shift-amount b1 v2*) |
intval-uright-shift - - = *UndefVal*

2 Stamp Typing

theory *Stamp*
imports *Values*
begin

The GraalVM compiler uses the Stamp class to store range and type information for a given node in the IR graph. We model the Stamp class as a

datatype, Stamp, and provide a number of functions on the datatype which correspond to the class methods within the compiler.

Stamp information is used in a variety of ways in optimizations, and so, we additionally provide a number of lemmas which help to prove future optimizations.

```
datatype Stamp =
  VoidStamp
  | IntegerStamp (stp-bits: nat) (stpi-lower: int) (stpi-upper: int)

  | KlassPointerStamp (stp-nonNull: bool) (stp-alwaysNull: bool)
  | MethodCountersPointerStamp (stp-nonNull: bool) (stp-alwaysNull: bool)
  | MethodPointersStamp (stp-nonNull: bool) (stp-alwaysNull: bool)
 | ObjectStamp (stp-type: string) (stp-exactType: bool) (stp-nonNull: bool) (stp-alwaysNull:
bool)
  | RawPointerStamp (stp-nonNull: bool) (stp-alwaysNull: bool)
  | IllegalStamp

fun is-stamp-empty :: Stamp ⇒ bool where
  is-stamp-empty (IntegerStamp b lower upper) = (upper < lower) |

  is-stamp-empty x = False
```

Just like the IntegerStamp class, we need to know that our lo/hi bounds fit into the given number of bits (either signed or unsigned). Our integer stamps have infinite lo/hi bounds, so if the lower bound is non-negative, we can assume that all values are positive, and the integer bits of a related value can be interpreted as unsigned. This is similar (but slightly more general) to what IntegerStamp.java does with its test: if (sameSignBounds()) in the unsignedUpperBound() method.

Note that this is a bit different and more accurate than what StampFactory.forUnsignedInteger does (it widens large unsigned ranges to the max signed range to allow all bit patterns) because its lo/hi values are only 64-bit.

```
fun valid-stamp :: Stamp ⇒ bool where
  valid-stamp (IntegerStamp bits lo hi) =
    (0 < bits ∧ bits ≤ 64 ∧
    fst (bit-bounds bits) ≤ lo ∧ lo ≤ snd (bit-bounds bits) ∧
    fst (bit-bounds bits) ≤ hi ∧ hi ≤ snd (bit-bounds bits)) |
  valid-stamp s = True

experiment begin
corollary bit-bounds 1 = (−1, 0) by simp
end
```

```

3 Graph Representation

3.1 IR Graph Nodes

theory *IRNodes*
imports
Values
begin

The GraalVM IR is represented using a graph data structure. Here we define the nodes that are contained within the graph. Each node represents a Node subclass in the GraalVM compiler, the node classes have annotated fields to indicate input and successor edges.

We represent these classes with each IRNode constructor explicitly labelling a reference to the node IDs that it stores as inputs and successors.

The inputs_of and successors_of functions partition those labelled references into input edges and successor edges of a node.

To identify each Node, we use a simple natural number index. Zero is always the start node in a graph. For human readability, within nodes we write INPUT (or special case thereof) instead of ID for input edges, and SUCC instead of ID for control-flow successor edges. Optional edges are handled as "INPUT option" etc.

3.2 IR Graph Node Hierarchy

theory *IRNodeHierarchy*
imports *IRNodes*
begin

It is helpful to introduce a node hierarchy into our formalization. Often the GraalVM compiler relies on explicit type checks to determine which operations to perform on a given node, we try to mimic the same functionality by using a suite of predicate functions over the IRNode class to determine inheritance.

As one would expect, the function is<ClassName>Type will be true if the node parameter is a subclass of the ClassName within the GraalVM compiler.

These functions have been automatically generated from the compiler.

3.3 IR Graph Type

theory *IRGraph*
imports
IRNodeHierarchy
Stamp
HOL−Library.FSet
HOL.Relation
begin

This theory defines the main Graal data structure - an entire IR Graph.

IRGraph is defined as a partial map with a finite domain. The finite domain is required to be able to generate code and produce an interpreter.

typedef *IRGraph* = $\{g :: ID \rightharpoonup (IRNode \times Stamp)\ .\ finite\ (dom\ g)\}$

3.3.1 Example Graphs

Example 1: empty graph (just a start and end node)

definition *start-end-graph*:: *IRGraph* **where**
start-end-graph = *irgraph* [(*0*, *StartNode None 1*, *VoidStamp*), (*1*, *ReturnNode None None*, *VoidStamp*)]

Example 2: public static int sq(int x) return x * x;
[1 P(0)] / [0 Start] [4 *] | / V / [5 Return]

```
definition eg2-sq :: IRGraph where
  eg2-sq = irgraph [
    (0, StartNode None 5, VoidStamp),
    (1, ParameterNode 0, default-stamp),
    (4, MulNode 1 1, default-stamp),
    (5, ReturnNode (Some 4) None, default-stamp)
   ]

value input-edges eg2-sq
value usages eg2-sq 1

end
```

3.4 Control-flow Graph Traversal

```
theory
  Traversal
imports
  IRGraph
begin

type-synonym Seen = ID set
```

nextEdge helps determine which node to traverse next by returning the first successor edge that isn't in the set of already visited nodes. If there is not an appropriate successor, None is returned instead.

```
fun nextEdge :: Seen ⇒ ID ⇒ IRGraph ⇒ ID option where
  nextEdge seen nid g =
    (let nids = (filter (λnid'. nid' ∉ seen) (successors-of (kind g nid))) in
     (if length nids > 0 then Some (hd nids) else None))
```

pred determines which node, if any, acts as the predecessor of another.

Merge nodes represent a special case where-in the predecessor exists as an input edge of the merge node, to simplify the traversal we treat only the first input end node as the predecessor, ignoring that multiple nodes may act as a successor.

For all other nodes, the predecessor is the first element of the predecessors set. Note that in a well-formed graph there should only be one element in the predecessor set.

```
fun pred :: IRGraph ⇒ ID ⇒ ID option where
  pred g nid = (case kind g nid of
    (MergeNode ends - -) ⇒ Some (hd ends) |
    - ⇒
      (if IRGraph.predecessors g nid = {}
        then None else
```

```
      Some (hd (sorted-list-of-set (IRGraph.predecessors g nid)))
    )
  )
```

Here we try to implement a generic fork of the control-flow traversal algorithm that was initially implemented for the ConditionalElimination phase

type-synonym *'a TraversalState* = (*ID* × *Seen* × *'a*)

5 Data-flow Semantics

theory *IRTreeEval*
imports
Graph.Stamp
begin

We define a tree representation of data-flow nodes, as an abstraction of the graph view.

Data-flow trees are evaluated in the context of a method state (currently called MapState in the theories for historical reasons).

The method state consists of the values for each method parameter, references to method parameters use an index of the parameter within the parameter list, as such we store a list of parameter values which are looked up at parameter references.

The method state also stores a mapping of node ids to values. The contents of this mapping is calculates during the traversal of the control flow graph.

As a concrete example, as the *SignedDivNode* can have side-effects (during division by zero), it is treated as part of the control-flow, since the data-flow phase is specified to be side-effect free. As a result, the control-flow semantics for *SignedDivNode* calculates the value of a node and maps the node identifier to the value within the method state. The data-flow semantics then just reads the value stored in the method state for the node.

5.2 Functions for re-calculating stamps

Note: in Java all integer calculations are done as 32 or 64 bit calculations. However, here we generalise the operators to allow any size calculations. Many operators have the same output bits as their inputs. However, the unary integer operators that are not *normal_unary* are narrowing or widening operators, so the result bits is specified by the operator. The binary integer operators are divided into three groups: (1) $binary\_fixed\_32$ operators always output 32 bits, (2) $binary\_shift\_ops$ operators output size is determined by their left argument, and (3) other operators output the same number of bits as both their inputs.

5.4 Data-flow Tree Refinement

We define the induced semantic equivalence relation between expressions. Note that syntactic equality implies semantic equivalence, but not vice versa.

definition *equiv-exprs* :: *IRExpr* $\Rightarrow$ *IRExpr* $\Rightarrow$ *bool* (- $\doteq$ - *55*) **where**
(*e1* $\doteq$ *e2*) = ($\forall$ *m p v*. (([*m*,*p*] $\vdash$ *e1* $\mapsto$ *v*) $\longleftrightarrow$ ([*m*,*p*] $\vdash$ *e2* $\mapsto$ *v*)))

We also prove that this is a total equivalence relation (*equivp equiv-exprs*) (HOL.Equiv_Relations), so that we can reuse standard results about equivalence relations.

lemma *equivp equiv-exprs*
apply (*auto simp add*: *equivp-def equiv-exprs-def*)
by (*metis equiv-exprs-def*)+

We define a refinement ordering over IRExpr and show that it is a preorder. Note that it is asymmetric because e2 may refer to fewer variables than e1.

instantiation *IRExpr* :: *preorder* **begin**

notation *less-eq* (**infix** $\sqsubseteq$ *65*)

definition
le-expr-def [*simp*]:
$(e_2 \leq e_1) \longleftrightarrow (\forall\ m\ p\ v.\ (([m,p] \vdash e_1 \mapsto v) \longrightarrow ([m,p] \vdash e_2 \mapsto v)))$

where $e_1 \sqsupseteq e_2 \equiv (e_2 \leq e_1)$

5.5 Stamp Masks

A stamp can contain additional range information in the form of masks. A stamp has an up mask and a down mask, corresponding to a the bits that may be set and the bits that must be set.

Examples: A stamp where no range information is known will have; an up mask of -1 as all bits may be set, and a down mask of 0 as no bits must be set.

A stamp known to be one should have; an up mask of 1 as only the first bit may be set, no others, and a down mask of 1 as the first bit must be set and no others.

We currently don't carry mask information in stamps, and instead assume correct masks to prove optimizations.

5.6.4 Example Data-flow Optimisations

5.6.5 Monotonicity of Expression Refinement

We prove that each subexpression position is monotonic. That is, optimizing a subexpression anywhere deep inside a top-level expression also optimizes that top-level expression.

Note that we might also be able to do this via reusing Isabelle's *mono* operator (HOL.Orderings theory), proving instantiations like $mono(UnaryExprop)$, but it is not obvious how to do this for both arguments of the binary expressions.

lemma *mono-unary*:
  assumes $x \geq x'$
  shows (*UnaryExpr op x*) ≥ (*UnaryExpr op x′*)
  using *UnaryExpr assms* **by** *auto*

lemma *mono-binary*:
  assumes $x \geq x'$
  assumes $y \geq y'$
  shows (*BinaryExpr op x y*) ≥ (*BinaryExpr op x′ y′*)
  using *BinaryExpr assms* **by** *auto*

lemma *never-void*:
  assumes [*m*, *p*] ⊢ *x* ↦ *xv*
  assumes *valid-value xv* (*stamp-expr xe*)
  shows *stamp-expr xe* ≠ *VoidStamp*
  using *valid-value.simps*

using *assms*(*2*) **by** *force*

lemma *compatible-trans*:
compatible x y ∧ *compatible y z* ⟹ *compatible x z*
by (*cases x*; *cases y*; *cases z*; *simp del*: *valid-stamp.simps*)

lemma *compatible-refl*:
compatible x y ⟹ *compatible y x*
using *compatible.elims*(*2*) **by** *fastforce*

lemma *mono-conditional*:
assumes $c \geq c'$

qed

5.7 Unfolding rules for evaltree quadruples down to bin-eval level

These rewrite rules can be useful when proving optimizations. They support top-down rewriting of each level of the tree into the lower-level bin_eval / $unary_eval$ level, simply by saying $unfoldingunfold_evaltree$.

lemma *unfold-const*:
shows ([*m*,*p*] ⊢ *ConstantExpr c* ↦ *v*) = (*wf-value v* ∧ *v* = *c*)

6.7 Dynamic Frames

This theory defines two operators, 'unchanged' and 'changeonly', that are useful for specifying which nodes in an IRGraph can change. The dynamic framing idea originates from 'Dynamic Frames' in software verification, started by Ioannis T. Kassios in "Dynamic frames: Support for framing, dependencies and sharing without restrictions", In FM 2006.

6.8.1 Extraction and Evaluation of Expression Trees is Deterministic.

First, we prove some extra rules that relate each type of IRNode to the corresponding IRExpr type that 'rep' will produce. These are very helpful

for proving that 'rep' is deterministic.

named-theorems *rep*

7.1 Object Heap

The heap model we introduce maps field references to object instances to runtime values. We use the H[f][p] heap representation. See *cite*{*heap−reps−2011*}.
We also introduce the DynamicHeap type which allocates new object references sequentially storing the next free object reference as 'Free'.

heapdef

type-synonym ('a, 'b) *Heap* = 'a ⇒ 'b ⇒ *Value*
type-synonym *Free* = *nat*
type-synonym ('a, 'b) *DynamicHeap* = ('a, 'b) *Heap* × *Free*

fun *h-load-field* :: 'a ⇒ 'b ⇒ ('a, 'b) *DynamicHeap* ⇒ *Value* **where**
h-load-field f r (*h*, *n*) = *h f r*

fun *h-store-field* :: 'a ⇒ 'b ⇒ *Value* ⇒ ('a, 'b) *DynamicHeap* ⇒ ('a, 'b) *DynamicHeap* **where**
h-store-field f r v (*h*, *n*) = (*h*(*f* := ((*h f*)(*r* := *v*))), *n*)

fun *h-new-inst* :: ('a, 'b) *DynamicHeap* ⇒ ('a, 'b) *DynamicHeap* × *Value* **where**
h-new-inst (*h*, *n*) = ((*h*,*n*+*1*), (*ObjRef* (*Some n*)))

type-synonym *FieldRefHeap* = (*string*, *objref*) *DynamicHeap*

definition new-heap :: ('a, 'b) *DynamicHeap* **where**
new-heap = ((λ*f*. λ*p*. *UndefVal*), *0*)

7.2 Intraprocedural Semantics

fun *find-index* :: 'a ⇒ 'a *list* ⇒ *nat* **where**
find-index - [] = *0* |
find-index v (*x* # *xs*) = (*if* (*x*=*v*) *then 0 else find-index v xs* + *1*)

fun *phi-list* :: *IRGraph* ⇒ *ID* ⇒ *ID list* **where**
phi-list g n =
(*filter* (λ*x*.(*is-PhiNode* (*kind g x*)))
(*sorted-list-of-set* (*usages g n*)))

fun *input-index* :: *IRGraph* ⇒ *ID* ⇒ *ID* ⇒ *nat* **where**
input-index g n n' = *find-index n'* (*inputs-of* (*kind g n*))

fun *phi-inputs* :: *IRGraph* ⇒ *nat* ⇒ *ID list* ⇒ *ID list* **where**
phi-inputs g i nodes = (*map* (λ*n*. (*inputs-of* (*kind g n*))!(*i* + *1*)) *nodes*)

fun *set-phis* :: *ID list* ⇒ *Value list* ⇒ *MapState* ⇒ *MapState* **where**
set-phis [] [] *m* = *m* |
set-phis (*n* # *xs*) (*v* # *vs*) *m* = (*set-phis xs vs* (*m*(*n* := *v*))) |
set-phis [] (*v* # *vs*) *m* = *m* |
set-phis (*x* # *xs*) [] *m* = *m*

Intraprocedural semantics are given as a small-step semantics.

Within the context of a graph, the configuration triple, (ID, MethodState, Heap), is related to the subsequent configuration.

7.5 Control-flow Semantics Theorems

theory *IRStepThms*
imports
IRStepObj

TreeToGraphThms
begin

We prove that within the same graph, a configuration triple will always transition to the same subsequent configuration. Therefore, our step semantics is deterministic.

7.5.1 Control-flow Step is Deterministic

8.4.1 Support Lemmas for Integer Stamps and Associated IntVal values

Valid int implies some useful facts.

lemma *valid-int-gives*:
assumes *valid-value (IntVal b val) stamp*
obtains *lo hi* **where** *stamp = IntegerStamp b lo hi ∧*
valid-stamp (IntegerStamp b lo hi) ∧
take-bit b val = val ∧
lo ≤ int-signed-value b val ∧ int-signed-value b val ≤ hi
using *assms*
by (*smt (z3) Value.distinct(7) Value.inject(1) valid-value.elims(1)*)

And the corresponding lemma where we know the stamp rather than the value.

lemma *valid-int-stamp-gives*:
assumes *valid-value val (IntegerStamp b lo hi)*
obtains *ival* **where** *val = IntVal b ival ∧*
valid-stamp (IntegerStamp b lo hi) ∧
take-bit b ival = ival ∧
lo ≤ int-signed-value b ival ∧ int-signed-value b ival ≤ hi
by (*metis assms valid-int valid-value.simps(1)*)

A valid int must have the expected number of bits.

lemma *valid-int-same-bits*:
assumes *valid-value (IntVal b val) (IntegerStamp bits lo hi)*
shows *b = bits*
by (*meson assms valid-value.simps(1)*)

A valid value means a valid stamp.

lemma *valid-int-valid-stamp*:
assumes *valid-value (IntVal b val) (IntegerStamp bits lo hi)*
shows *valid-stamp (IntegerStamp bits lo hi)*
by (*metis assms valid-value.simps(1)*)

A valid int means a valid non-empty stamp.

lemma *valid-int-not-empty*:

assumes *valid-value* (*IntVal b val*) (*IntegerStamp bits lo hi*)
shows *lo* ≤ *hi*
by (*metis assms order.trans valid-value.simps*(*1*))

A valid int fits into the given number of bits (and other bits are zero).

lemma *valid-int-fits*:
assumes *valid-value* (*IntVal b val*) (*IntegerStamp bits lo hi*)
shows *take-bit bits val* = *val*
by (*metis assms valid-value.simps*(*1*))

lemma *valid-int-is-zero-masked*:
assumes *valid-value* (*IntVal b val*) (*IntegerStamp bits lo hi*)
shows *and val* (*not* (*mask bits*)) = *0*
by (*metis* (*no-types*, *lifting*) *assms bit.conj-cancel-right take-bit-eq-mask valid-int-fits*

word-bw-assocs(*1*) *word-log-esimps*(*1*))

Unsigned ints have bounds 0 up to $2^b its$.

lemma *valid-int-unsigned-bounds*:
assumes *valid-value* (*IntVal b val*) (*IntegerStamp bits lo hi*)

shows *uint val* < *2* ^ *bits*
by (*metis assms*(*1*) *mask-eq-iff take-bit-eq-mask valid-value.simps*(*1*))

Signed ints have the usual two-complement bounds.

lemma *valid-int-signed-upper-bound*:
assumes *valid-value* (*IntVal b val*) (*IntegerStamp bits lo hi*)
shows *int-signed-value bits val* < *2* ^ (*bits* − *1*)
by (*metis* (*mono-tags*, *opaque-lifting*) *diff-le-mono int-signed-value.simps less-imp-diff-less*

linorder-not-le one-le-numeral order-less-le-trans power-increasing signed-take-bit-int-less-exp-word sint-lt)

Proofs.Bisimulation
begin

11.1 Individual Elimination Rules

The set of rules used for determining whether a condition *q1*::$'a$ implies another condition *q2*::$'a$ or its negation. These rules are used for conditional elimination.

inductive *impliesx* :: *IRExpr* ⇒ *IRExpr* ⇒ *bool* (- ⇛ -) **and**
impliesnot :: *IRExpr* ⇒ *IRExpr* ⇒ *bool* (- ⇛¬ -) **where**
q-imp-q:
$q \Rrightarrow q$ |
eq-impliesnot-less:
(*BinaryExpr BinIntegerEquals x y*) ⇛¬ (*BinaryExpr BinIntegerLessThan x y*) |
eq-impliesnot-less-rev:
(*BinaryExpr BinIntegerEquals x y*) ⇛¬ (*BinaryExpr BinIntegerLessThan y x*) |
less-impliesnot-rev-less:
(*BinaryExpr BinIntegerLessThan x y*) ⇛¬ (*BinaryExpr BinIntegerLessThan y x*)
|
less-impliesnot-eq:
(*BinaryExpr BinIntegerLessThan x y*) ⇛¬ (*BinaryExpr BinIntegerEquals x y*) |
less-impliesnot-eq-rev:
(*BinaryExpr BinIntegerLessThan x y*) ⇛¬ (*BinaryExpr BinIntegerEquals y x*) |
negate-true:
$[\![x \Rrightarrow\neg\ y]\!] \Longrightarrow x \Rrightarrow$ (*UnaryExpr UnaryLogicNegation y*) |
negate-false:
$[\![x \Rrightarrow y]\!] \Longrightarrow x \Rrightarrow\neg$ (*UnaryExpr UnaryLogicNegation y*)

The relation *q1*::*IRExpr* ⇛ *q2*::*IRExpr* indicates that the implication (*q1*::*bool*)

$\longrightarrow$ (*q2*::*bool*) is known true (i.e. universally valid), and the relation *q1*::*IRExpr* $\Rrightarrow\neg$ *q2*::*IRExpr* indicates that the implication (*q1*::*bool*) $\longrightarrow$ (*q2*::*bool*) is known false (i.e. (*q1*::*bool*) $\longrightarrow \neg$ (*q2*::*bool*) is universally valid. If neither *q1*::*IRExpr* $\Rrightarrow$ *q2*::*IRExpr* nor *q1*::*IRExpr* $\Rrightarrow\neg$ *q2*::*IRExpr* then the status is unknown. Only the known true and known false cases can be used for conditional elimination.

fun *implies-valid* :: *IRExpr* $\Rightarrow$ *IRExpr* $\Rightarrow$ *bool* (**infix** $\rightarrowtail$ *50*) **where**
  implies-valid q1 q2 =
    ($\forall$ *m p v1 v2*. ([*m*, *p*] $\vdash$ *q1* $\mapsto$ *v1*) $\wedge$ ([*m*,*p*] $\vdash$ *q2* $\mapsto$ *v2*) $\longrightarrow$
          (*val-to-bool v1* $\longrightarrow$ *val-to-bool v2*))

fun *impliesnot-valid* :: *IRExpr* $\Rightarrow$ *IRExpr* $\Rightarrow$ *bool* (**infix** $\rightarrowtail\!\!\!\!\mid$ *50*) **where**
  impliesnot-valid q1 q2 =
    ($\forall$ *m p v1 v2*. ([*m*, *p*] $\vdash$ *q1* $\mapsto$ *v1*) $\wedge$ ([*m*,*p*] $\vdash$ *q2* $\mapsto$ *v2*) $\longrightarrow$
          (*val-to-bool v1* $\longrightarrow \neg$*val-to-bool v2*))

The relation (*q1*::*IRExpr*) $\rightarrowtail$ (*q2*::*IRExpr*) means (*q1*::*bool*) $\longrightarrow$ (*q2*::*bool*) is universally valid, and the relation (*q1*::*IRExpr*) $\rightarrowtail\!\!\!\!\mid$ (*q2*::*IRExpr*) means (*q1*::*bool*) $\longrightarrow \neg$ (*q2*::*bool*) is universally valid.

We introduce a type *TriState*::′*a* (as in the GraalVM compiler) to represent when static analysis can tell us information about the value of a Boolean expression. If *Unknown*::′*a* then no information can be inferred and if *KnownTrue*::′*a*/*KnownFalse*::′*a* one can infer the expression is always true/false.

datatype *TriState* = *Unknown* | *KnownTrue* | *KnownFalse*

The implies relation corresponds to the LogicNode.implies method from the compiler which attempts to infer when one logic nodes value can be inferred from a known logic node.

inductive *implies* :: *IRGraph* ⇒ *IRNode* ⇒ *IRNode* ⇒ *TriState* ⇒ *bool*

The following relation corresponds to the UnaryOpLogicNode.tryFold and BinaryOpLogicNode.tryFold methods and their associated concrete implementations.

The relation determines if a logic operation can be shown true or false through the stamp typing information.

inductive *tryFold* :: *IRNode* $\Rightarrow$ (*ID* $\Rightarrow$ *Stamp*) $\Rightarrow$ *bool* $\Rightarrow$ *bool*
where
⟦*alwaysDistinct* (*stamps x*) (*stamps y*)⟧
$\Longrightarrow$ *tryFold* (*IntegerEqualsNode x y*) *stamps False* |
⟦*neverDistinct* (*stamps x*) (*stamps y*)⟧
$\Longrightarrow$ *tryFold* (*IntegerEqualsNode x y*) *stamps True* |
⟦*is-IntegerStamp* (*stamps x*);
is-IntegerStamp (*stamps y*);
stpi-upper (*stamps x*) $<$ *stpi-lower* (*stamps y*)⟧
$\Longrightarrow$ *tryFold* (*IntegerLessThanNode x y*) *stamps True* |
⟦*is-IntegerStamp* (*stamps x*);
is-IntegerStamp (*stamps y*);
stpi-lower (*stamps x*) $\geq$ *stpi-upper* (*stamps y*)⟧
$\Longrightarrow$ *tryFold* (*IntegerLessThanNode x y*) *stamps False*

Proofs that show that when the stamp lookup function is well-formed, the tryFold relation correctly predicts the output value with respect to our evaluation semantics.

inductive-cases *StepE*:
g, *p* ⊢ (*nid*,*m*,*h*) → (*nid'*,*m'*,*h*)

Perform conditional elimination rewrites on the graph for a particular node.

In order to determine conditional eliminations appropriately the rule needs two data structures produced by static analysis. The first parameter is the set of IRNodes that we know result in a true value when evaluated. The second parameter is a mapping from node identifiers to the flow-sensitive stamp.

The relation transforms the third parameter to the fifth parameter for a node identifier which represents the fourth parameter.

type-synonym *StampFlow* = (*ID* ⇒ *Stamp*) *list*

nextEdge helps determine which node to traverse next by returning the first successor edge that isn't in the set of already visited nodes. If there is not an appropriate successor, None is returned instead.

fun *nextEdge* :: *Seen* ⇒ *ID* ⇒ *IRGraph* ⇒ *ID option* **where**
nextEdge seen nid g =
(*let nids* = (*filter* (λ*nid'*. *nid'* ∉ *seen*) (*successors-of* (*kind g nid*))) *in*
(*if length nids* > *0 then Some* (*hd nids*) *else None*))

pred determines which node, if any, acts as the predecessor of another.

Merge nodes represent a special case where-in the predecessor exists as an input edge of the merge node, to simplify the traversal we treat only the first input end node as the predecessor, ignoring that multiple nodes may act as a successor.

For all other nodes, the predecessor is the first element of the predecessors

set. Note that in a well-formed graph there should only be one element in the predecessor set.

```
fun pred :: IRGraph ⇒ ID ⇒ ID option where
  pred g nid = (case kind g nid of
    (MergeNode ends - -) ⇒ Some (hd ends) |
    - ⇒
      (if IRGraph.predecessors g nid = {}
        then None else
        Some (hd (sorted-list-of-set (IRGraph.predecessors g nid)))
      )
  )
```

When the basic block of an if statement is entered, we know that the condition of the preceding if statement must be true. As in the GraalVM compiler, we introduce the registerNewCondition funciton which roughly corresponds to the ConditionalEliminationPhase.registerNewCondition. This method updates the flow-sensitive stamp information based on the condition which we know must be true.

```
fun clip-upper :: Stamp ⇒ int ⇒ Stamp where
  clip-upper (IntegerStamp b l h) c = (IntegerStamp b l c) |
  clip-upper s c = s
fun clip-lower :: Stamp ⇒ int ⇒ Stamp where
  clip-lower (IntegerStamp b l h) c = (IntegerStamp b c h) |
  clip-lower s c = s

fun registerNewCondition :: IRGraph ⇒ IRNode ⇒ (ID ⇒ Stamp) ⇒ (ID ⇒
Stamp) where

  registerNewCondition g (IntegerEqualsNode x y) stamps =
    (stamps
      (x := join (stamps x) (stamps y)))
      (y := join (stamps x) (stamps y)) |

  registerNewCondition g (IntegerLessThanNode x y) stamps =
    (stamps
      (x := clip-upper (stamps x) (stpi-lower (stamps y))))
      (y := clip-lower (stamps y) (stpi-upper (stamps x))) |
  registerNewCondition g - stamps = stamps

fun hdOr :: 'a list ⇒ 'a ⇒ 'a where
  hdOr (x # xs) de = x |
  hdOr [] de = de
```

The Step relation is a small-step traversal of the graph which handles transitions between individual nodes of the graph.

It relates a pairs of tuple of the current node, the set of seen nodes, the always true stack of IfNode conditions, and the flow-sensitive stamp information.

```
inductive Step
```

:: *IRGraph* ⇒ (*ID* × *Seen* × *Conditions* × *StampFlow*) ⇒ (*ID* × *Seen* × *Conditions* × *StampFlow*) *option* ⇒ *bool*
for *g* **where**
— Hit a BeginNode with an IfNode predecessor which represents the start of a basic block for the IfNode. 1. nid' will be the successor of the begin node. 2. Find the first and only predecessor. 3. Extract condition from the preceding IfNode. 4. Negate condition if the begin node is second branch (we've taken the else branch of the condition) 5. Add the condition or the negated condition to stack 6. Perform any stamp updates based on the condition using the registerNewCondition function and place them on the top of the stack of stamp information
