

Veriopt

July 6, 2021

Abstract

The Veriopt project aims to prove the optimization pass of the GraalVM compiler. The GraalVM compiler includes a sophisticated Intermediate Representation (IR) in the form of a sea-of-nodes based graph structure. We first define the IR graph structure in the Isabelle/HOL interactive theorem prover. We subsequently give the evaluation of the structure a semantics based on the current understanding of the purpose of each IR graph node. Optimization phases are then encoded including the static analysis passes required for an optimization. Each optimization phase is proved to be correct by proving that a bisimulation exists between the unoptimized and optimized graphs. The following document has been automatically generated from the Isabelle/HOL source to provide a very comprehensive definition of the semantics and optimizations introduced by the Veriopt project.

1 Runtime Values and Arithmetic

```

theory Values2
  imports
    HOL-Library.Word
    HOL-Library.Signed-Division
    HOL-Library.Float
    HOL-Library.LaTeXsugar
  begin

```

In order to properly implement the IR semantics we first introduce a new type of runtime values. Our evaluation semantics are defined in terms of these runtime values. These runtime values represent the full range of primitive types currently allowed by our semantics, ranging from basic integer types to object references and eventually arrays.

An object reference is an option type where the None object reference points to the static fields. This is examined more closely in our definition of the heap.

Java supports 64, 32, 16, 8 signed ints, plus 1 bit (boolean) ints. Our Value type models this by keeping the value as an infinite precision signed int, but also carrying along the number of bits allowed.

So each $(\text{IntVal } b \ v)$ should satisfy the invariants:

$$b \in \{1::'a, 8::'a, 16::'a, 32::'a, 64::'a\}$$

$$1 < b \implies v \equiv \text{scast } (\text{signed-take-bit } b \ v)$$

```

type-synonym int64 = 64 word — long
type-synonym int32 = 32 word — int
type-synonym int16 = 16 word — short
type-synonym int8 = 8 word — char
type-synonym int1 = 1 word — boolean

```

```

type-synonym objref = nat option

```

```

datatype Value =
  UndefVal |
  IntVal32 int32 |
  IntVal64 int64 |
  FloatVal float |
  ObjRef objref |
  ObjStr string

```

We define integer values to be well-formed when their bit size is valid and their integer value is able to fit within the bit size. This is defined using the *wf-value* function.

— Check that a signed int value does not overflow b bits.

```

fun fits-into-n :: nat  $\Rightarrow$  int  $\Rightarrow$  bool where
  fits-into-n b val = (( $-(2^{b-1}) \leq val$ )  $\wedge$  ( $val < (2^b)$ ))

```

```
fun wf-bool :: Value  $\Rightarrow$  bool where
  wf-bool (IntVal32 v) = (v = 0  $\vee$  v = 1) |
  wf-bool - = False
```

```
fun val-to-bool :: Value  $\Rightarrow$  bool where
  val-to-bool (IntVal32 v) = (v = 1) |
  val-to-bool - = False
```

```
fun bool-to-val :: bool  $\Rightarrow$  Value where
  bool-to-val True = (IntVal32 1) |
  bool-to-val False = (IntVal32 0)
```

```
value sint(word-of-int (1) :: int1)
```

We need to introduce arithmetic operations which agree with the JVM.

Within the JVM, bytecode arithmetic operations are performed on 32 or 64 bit integers, unboxing where appropriate.

The following collection of intval functions correspond to the JVM arithmetic operations.

```
fun intval-add32 :: Value  $\Rightarrow$  Value  $\Rightarrow$  Value where
  intval-add32 (IntVal32 v1) (IntVal32 v2) = (IntVal32 (v1+v2)) |
  intval-add32 - - =.UndefVal
```

```
fun intval-add64 :: Value  $\Rightarrow$  Value  $\Rightarrow$  Value where
  intval-add64 (IntVal64 v1) (IntVal64 v2) = (IntVal64 (v1+v2)) |
  intval-add64 - - =.UndefVal
```

```
fun intval-add :: Value  $\Rightarrow$  Value  $\Rightarrow$  Value where
  intval-add (IntVal32 v1) (IntVal32 v2) = (IntVal32 (v1+v2)) |
  intval-add (IntVal64 v1) (IntVal64 v2) = (IntVal64 (v1+v2)) |
  intval-add - - =.UndefVal

2 Nodes

2.1 Types of Nodes

```

theory IRNodes2
  imports
    Values2
begin

```

The GraalVM IR is represented using a graph data structure. Here we define the nodes that are contained within the graph. Each node represents a Node subclass in the GraalVM compiler, the node classes have annotated fields to indicate input and successor edges.

We represent these classes with each IRNode constructor explicitly labelling a reference to the node IDs that it stores as inputs and successors.

The `inputs_of` and `successors_of` functions partition those labelled references into input edges and successor edges of a node.

To identify each Node, we use a simple natural number index. Zero is always the start node in a graph. For human readability, within nodes we write INPUT (or special case thereof) instead of ID for input edges, and SUCC instead of ID for control-flow successor edges. Optional edges are handled as "INPUT option" etc.

```

2.2 Hierarchy of Nodes

```

theory IRNodeHierarchy
imports IRNodes2
begin

```

It is helpful to introduce a node hierarchy into our formalization. Often the GraalVM compiler relies on explicit type checks to determine which operations to perform on a given node, we try to mimic the same functionality by using a suite of predicate functions over the IRNode class to determine inheritance.

As one would expect, the function `is<ClassName>Type` will be true if the node parameter is a subclass of the `ClassName` within the GraalVM compiler.

These functions have been automatically generated from the compiler.

```

3 Stamp Typing

```

theory Stamp2
  imports Values2
begin

```

The GraalVM compiler uses the Stamp class to store range and type information for a given node in the IR graph. We model the Stamp class as a datatype, Stamp, and provide a number of functions on the datatype which correspond to the class methods within the compiler.

Stamp information is used in a variety of ways in optimizations, and so, we additionally provide a number of lemmas which help to prove future optimizations.

```
datatype Stamp =
  VoidStamp
| IntegerStamp (stp-bits: nat) (stpi-lower: int) (stpi-upper: int)

| KlassPointerStamp (stp-nonNull: bool) (stp-alwaysNull: bool)
| MethodCountersPointerStamp (stp-nonNull: bool) (stp-alwaysNull: bool)
| MethodPointersStamp (stp-nonNull: bool) (stp-alwaysNull: bool)
| ObjectStamp (stp-type: string) (stp-exactType: bool) (stp-nonNull: bool) (stp-alwaysNull:
bool)
| RawPointerStamp (stp-nonNull: bool) (stp-alwaysNull: bool)
| IllegalStamp
```

```
fun bit-bounds :: nat  $\Rightarrow$  (int  $\times$  int) where
  bit-bounds bits = (((2 ^ bits) div 2) * -1, ((2 ^ bits) div 2) - 1)
```

— A stamp which includes the full range of the type

```
fun unrestricted-stamp :: Stamp  $\Rightarrow$  Stamp where
  unrestricted-stamp VoidStamp = VoidStamp |

4 Graph Representation

theory *IRGraph*
imports
IRNodeHierarchy
Stamp2
HOL-Library.FSet
HOL.Relation
begin

This theory defines the main Graal data structure - an entire IR Graph.

IRGraph is defined as a partial map with a finite domain. The finite domain is required to be able to generate code and produce an interpreter.

typedef *IRGraph* = {*g* :: *ID* \rightarrow (*IRNode* \times *Stamp*) . *finite* (*dom g*)}

 (1, *ParameterNode* 0, *default-stamp*),
 (4, *MulNode* 1 1, *default-stamp*),

```
(5, ReturnNode (Some 4) None, default-stamp)
]
```

```
value input-edges eg2-sq
value usages eg2-sq 1

end
```

5 Data-flow Semantics

```
theory IRTreeEval
  imports
    Graph.IRGraph
begin
```

We define a tree representation of data-flow nodes, as an abstraction of the graph view.

Data-flow trees are evaluated in the context of a method state (currently called MapState in the theories for historical reasons).

The method state consists of the values for each method parameter, references to method parameters use an index of the parameter within the parameter list, as such we store a list of parameter values which are looked up at parameter references.

The method state also stores a mapping of node ids to values. The contents of this mapping is calculates during the traversal of the control flow graph.

As a concrete example, as the *SignedDivNode* can have side-effects (during division by zero), it is treated as part of the control-flow, since the data-flow phase is specified to be side-effect free. As a result, the control-flow semantics for *SignedDivNode* calculates the value of a node and maps the node identifier to the value within the method state. The data-flow semantics then just reads the value stored in the method state for the node.

```
type-synonym MapState = ID  $\Rightarrow$  Value
type-synonym Params = Value list
```

```
definition new-map-state :: MapState where
  new-map-state = ( $\lambda x$ ..UndefVal)
```

```
fun val-to-bool :: Value  $\Rightarrow$  bool where
  val-to-bool (IntVal32 val) = (if val = 0 then False else True) |
  val-to-bool v = False
```

```
fun bool-to-val :: bool  $\Rightarrow$  Value where
  bool-to-val True = (IntVal32 1) |
```

bool-to-val False = (IntVal32 0)

```
fun find-index :: 'a ⇒ 'a list ⇒ nat where
  find-index - [] = 0 |
  find-index v (x # xs) = (if (x=v) then 0 else find-index v xs + 1)
```

```
fun phi-list :: IRGraph ⇒ ID ⇒ ID list where
  phi-list g nid =
    (filter (λx.(is-PhiNode (kind g x)))
     (sorted-list-of-set (usages g nid)))
```

```
fun input-index :: IRGraph ⇒ ID ⇒ ID ⇒ nat where
  input-index g n n' = find-index n' (inputs-of (kind g n))
```

```
fun phi-inputs :: IRGraph ⇒ nat ⇒ ID list ⇒ ID list where

5.3 Data-flow Tree Refinement

We define the induced semantic equivalence relation between expressions. Note that syntactic equality implies semantic equivalence, but not vice versa.

definition *equiv-exprs* :: IRExp \Rightarrow IRExp \Rightarrow bool ($- \doteq -$ 55) **where**
 $(e1 \doteq e2) = (\forall\ m\ p\ v. ([m, p] \vdash e1 \mapsto v) \longleftrightarrow ([m, p] \vdash e2 \mapsto v))$

We also prove that this is a total equivalence relation (*equivp equiv-exprs*) (HOL.Equiv_Relations), so that we can reuse standard results about equivalence relations.

lemma *equivp equiv-exprs*

```

  apply (auto simp add: equivp-def equiv-exprs-def)

```

```

  by (metis equiv-exprs-def)+

```

We define a refinement ordering over IRExp and show that it is a preorder. Note that it is asymmetric because $e2$ may refer to fewer variables than $e1$.

```

instantiation IRExp :: preorder begin

```

definition

le-expr-def [simp]: $(e1 \leq e2) \longleftrightarrow (\forall m p v. ([m,p] \vdash e1 \mapsto v) \longrightarrow ([m,p] \vdash e2 \mapsto v))$

definition

lt-expr-def [simp]: $(e1 < e2) \longleftrightarrow (e1 \leq e2 \wedge \neg (e1 \doteq e2))$

instance proof

```

fix x y z :: IRExp
show x < y  $\longleftrightarrow$  x  $\leq$  y  $\wedge$   $\neg$  (y  $\leq$  x) by (simp add: equiv-exprs-def; auto)
show x  $\leq$  x by simp
show x  $\leq$  y  $\implies$  y  $\leq$  z  $\implies$  x  $\leq$  z by simp
qed
end

end

```

6 Data-flow Expression-Tree Theorems

theory *IRTreeEvalThms*

imports

Semantics.IRTreeEval

begin

6.1 Extraction and Evaluation of Expression Trees is Deterministic.

First, we prove some extra rules that relate each type of *IRNode* to the corresponding *IRExp* type that 'rep' will produce. These are very helpful for proving that 'rep' is deterministic.

lemma *rep-constant*:

```

g  $\vdash$  n  $\triangleright$  e  $\implies$ 
  kind g n = ConstantNode c  $\implies$ 
  e = ConstantExpr c
by (induction rule: rep.induct; auto)

```

lemma *rep-parameter*:

```

g  $\vdash$  n  $\triangleright$  e  $\implies$ 
  kind g n = ParameterNode i  $\implies$ 
  ( $\exists s. e = \text{ParameterExpr } i s$ )
by (induction rule: rep.induct; auto)

```

lemma *rep-conditional*:

```

g  $\vdash$  n  $\triangleright$  e  $\implies$ 
  kind g n = ConditionalNode c t f  $\implies$ 
  ( $\exists ce te fe. e = \text{ConditionalExpr } ce te fe$ )
by (induction rule: rep.induct; auto)

```

lemma *rep-abs*:

$g \vdash n \triangleright e \implies$
 $kind\ g\ n = AbsNode\ x \implies$
 $(\exists xe. e = UnaryExpr\ UnaryAbs\ xe)$
by (*induction rule*: *rep.induct*; *auto*)

lemma *rep-not*:

$g \vdash n \triangleright e \implies$
 $kind\ g\ n = NotNode\ x \implies$
 $(\exists xe. e = UnaryExpr\ UnaryNot\ xe)$
by (*induction rule*: *rep.induct*; *auto*)

lemma *rep-negate*:

```

6.3 Monotonicity of Expression Optimization

We prove that each subexpression position is monotonic. That is, optimizing a subexpression anywhere deep inside a top-level expression also optimizes that top-level expression.

Note that we might also be able to do this via reusing Isabelle's 'mono' operator (HOL.Orderings theory), proving instantiations like 'mono (UnaryExpr op)', but it is not obvious how to do this for both arguments of the binary expressions.

```

lemma mono-unary:
  assumes  $e \leq e'$ 
  shows (UnaryExpr op e) ≤ (UnaryExpr op e')
  using UnaryExpr assms by auto

```

```

lemma mono-binary:
  assumes  $x \leq x'$ 
  assumes  $y \leq y'$ 
  shows (BinaryExpr op x y) ≤ (BinaryExpr op x' y')
  using BinaryExpr assms by auto

```

```

lemma mono-conditional:
  assumes  $ce \leq ce'$ 
  assumes  $te \leq te'$ 
  assumes  $fe \leq fe'$ 
  shows (ConditionalExpr ce te fe) ≤ (ConditionalExpr ce' te' fe')
proof (simp only: le-expr-def; (rule allI)+; rule impI)
  fix  $m\ p\ v$ 
  assume  $a: [m, p] \vdash \text{ConditionalExpr } ce\ te\ fe \mapsto v$ 
  then obtain  $cond$  where  $ce: [m, p] \vdash ce \mapsto cond$  by auto
  then have  $ce': [m, p] \vdash ce' \mapsto cond$  using assms by auto
  define  $branch$  where  $b: branch = (if\ val\text{-}to\text{-}bool\ cond\ then\ te\ else\ fe)$ 
  define  $branch'$  where  $b': branch' = (if\ val\text{-}to\text{-}bool\ cond\ then\ te'\ else\ fe')$ 
  then have  $[m, p] \vdash branch \mapsto v$  using  $a\ b\ ce\ evalDet$  by blast
  then have  $[m, p] \vdash branch' \mapsto v$  using assms  $b\ b'$  by auto

7 Control-flow Semantics

```

theory IRStepObj
  imports
    IRTreeEval
begin

```

7.1 Heap

The heap model we introduce maps field references to object instances to runtime values. We use the $H[f][p]$ heap representation. See *\cite{heap-reps-2011}*. We also introduce the `DynamicHeap` type which allocates new object references sequentially storing the next free object reference as `'Free'`.

```

type-synonym ('a, 'b) Heap = 'a  $\Rightarrow$  'b  $\Rightarrow$  Value
type-synonym Free = nat
type-synonym ('a, 'b) DynamicHeap = ('a, 'b) Heap  $\times$  Free

fun h-load-field :: 'a  $\Rightarrow$  'b  $\Rightarrow$  ('a, 'b) DynamicHeap  $\Rightarrow$  Value where
  h-load-field f r (h, n) = h f r

fun h-store-field :: 'a  $\Rightarrow$  'b  $\Rightarrow$  Value  $\Rightarrow$  ('a, 'b) DynamicHeap  $\Rightarrow$  ('a, 'b) DynamicHeap where
  h-store-field f r v (h, n) = (h(f := ((h f)(r := v))), n)

fun h-new-inst :: ('a, 'b) DynamicHeap  $\Rightarrow$  ('a, 'b) DynamicHeap  $\times$  Value where
  h-new-inst (h, n) = ((h, n + 1), (ObjRef (Some n)))

type-synonym FieldRefHeap = (string, objref) DynamicHeap

definition new-heap :: ('a, 'b) DynamicHeap where
  new-heap = (( $\lambda f. \lambda p. \text{UndefVal}$ ), 0)

```

7.2 Intraprocedural Semantics

Intraprocedural semantics are given as a small-step semantics. Within the context of a graph, the configuration triple, (*ID*, *MethodState*, *Heap*), is related to the subsequent configuration.

```

inductive step :: IRGraph  $\Rightarrow$  Params  $\Rightarrow$  (ID  $\times$  MapState  $\times$  FieldRefHeap)  $\Rightarrow$  (ID
 $\times$  MapState  $\times$  FieldRefHeap)  $\Rightarrow$  bool
  ( $\_, \_ \vdash \_ \rightarrow \_$  55) for g p where
