begin

lemma $-((x{::}\mathit{float}){-}y) = (y{-}x)$
  by *simp*

In order to properly implement the IR semantics we first introduce a type that represents runtime values. These runtime values represent the full range of primitive types currently allowed by our semantics, ranging from basic integer types to object references and arrays.

Note that Java supports 64, 32, 16, 8 signed ints, plus 1 bit (boolean) ints, and char is 16-bit unsigned. E.g. an 8-bit stamp has a default range of -128..+127. And a 1-bit stamp has a default range of -1..0, surprisingly.

During calculations the smaller sizes are sign-extended to 32 bits, but explicit widening nodes will do that, so most binary calculations should see equal input sizes.

An object reference is an option type where the *None* object reference points to the static fields. This is examined more closely in our definition of the heap.

type-synonym *int64 = 64 word* — long
type-synonym *int32 = 32 word* — int
type-synonym *int16 = 16 word* — short
type-synonym *int8 = 8 word* — char
type-synonym *int1 = 1 word* — boolean

abbreviation *valid-int-widths* :: *nat set* **where**
  valid-int-widths $\equiv$ { *1*, *8*, *16*, *32*, *64* }

Option 2: explicit width stored with each integer value. However, this does not help us to distinguish between short (signed) and char (unsigned).

typedef *IntWidth* = { *w* :: *nat* . *w=1* $\lor$ *w=8* $\lor$ *w=16* $\lor$ *w=32* $\lor$ *w=64* }
  by *blast*

setup-lifting *type-definition-IntWidth*

lift-definition *IntWidthBits* :: *IntWidth* $\Rightarrow$ *nat*
  is $\lambda w.\ w$.

Option 3: explicit type stored with each integer value.

1.1 Arithmetic Operators

We need to introduce arithmetic operations which agree with the JVM.

Within the JVM, bytecode arithmetic operations are performed on 32 or 64 bit integers, unboxing where appropriate.

The following collection of intval functions correspond to the JVM arithmetic operations. We merge the 32 and 64 bit operations into a single

function, even though the stamp of each IRNode tells us exactly what the bit widths will be. These merged functions make it easier to do the instantiation of Value as 'plus', etc. It might be worse for reasoning, because it could cause more case analysis, but this does not seem to be a problem in practice.

fun *intval-add* :: *Value* ⇒ *Value* ⇒ *Value* **where**
  intval-add (*IntVal b1 v1*) (*IntVal b2 v2*) =
    (*if b1* = *b2 then IntVal b1* (*take-bit b1* (*v1*+*v2*)) *else UndefVal*) |
  intval-add - - = *UndefVal*

fun *intval-sub* :: *Value* ⇒ *Value* ⇒ *Value* **where**
  intval-sub (*IntVal b1 v1*) (*IntVal b2 v2*) = *new-int-bin b1 b2* (*v1*−*v2*) |
  intval-sub - - = *UndefVal*

  intval-logic-negation (IntVal b v) = new-int b (logic-negate v) |
  intval-logic-negation - = UndefVal

1.3 Narrowing and Widening Operators

Note: we allow these operators to have inBits=outBits, because the Graal compiler also seems to allow that case, even though it should rarely / never arise in practice.

value *sint(signed-take-bit 0 (1 :: int32))*

fun *intval-narrow :: nat ⇒ nat ⇒ Value ⇒ Value* **where**
  intval-narrow inBits outBits (IntVal b v) =
    (if inBits = b ∧ 0 < outBits ∧ outBits ≤ inBits ∧ inBits ≤ 64
      then new-int outBits v
      else UndefVal) |

intval-narrow - - - = UndefVal

value *intval*(*intval-narrow 16 8* (*IntVal32* (*512 − 2*)))

value *sint* (*signed-take-bit 7* ((*256 + 128*) :: *int64*))

fun *intval-sign-extend* :: *nat ⇒ nat ⇒ Value ⇒ Value* **where**
  intval-sign-extend inBits outBits (*IntVal b v*) =
    (*if inBits = b ∧ 0 < inBits ∧ inBits ≤ outBits ∧ outBits ≤ 64*
    then new-int outBits (*signed-take-bit* (*inBits − 1*) *v*)
    else UndefVal) |
  intval-sign-extend - - - = UndefVal

fun *intval-zero-extend* :: *nat ⇒ nat ⇒ Value ⇒ Value* **where**
  intval-zero-extend inBits outBits (*IntVal b v*) =
    (*if inBits = b ∧ 0 < inBits ∧ inBits ≤ outBits ∧ outBits ≤ 64*
    then new-int outBits (*take-bit inBits v*)
    else UndefVal) |
  intval-zero-extend - - - = UndefVal

Some well-formedness results to help reasoning about narrowing and widening operators

lemma *intval-narrow-ok*:
  assumes *intval-narrow inBits outBits val ≠ UndefVal*
  shows *0 < outBits ∧ outBits ≤ inBits ∧ inBits ≤ 64 ∧ outBits ≤ 64 ∧*
    is-IntVal val ∧
    intval-bits val = inBits
  using *assms intval-narrow.simps neq0-conv intval-bits.simps*
  by (*metis Value.disc*(*2*) *intval-narrow.elims le-trans*)

lemma *intval-sign-extend-ok*:
  assumes *intval-sign-extend inBits outBits val ≠ UndefVal*
  shows *0 < inBits ∧*
    inBits ≤ outBits ∧ outBits ≤ 64 ∧
    is-IntVal val ∧
    intval-bits val = inBits
  using *assms intval-sign-extend.simps neq0-conv*
  by (*metis intval-bits.simps intval-sign-extend.elims is-IntVal-def*)

lemma *intval-zero-extend-ok*:
  assumes *intval-zero-extend inBits outBits val ≠ UndefVal*
  shows *0 < inBits ∧*
    inBits ≤ outBits ∧ outBits ≤ 64 ∧
    is-IntVal val ∧
    intval-bits val = inBits

using *assms intval-sign-extend.simps neq0-conv*
by (*metis intval-bits.simps intval-zero-extend.elims is-IntVal-def*)

1.4 Bit-Shifting Operators

definition *shiftl* (**infix** $<<$ *75*) **where**
  shiftl w n = (push-bit n) w

lemma *shiftl-power*[*simp*]: $(x::('a::len)\ word) * (2\ \hat{}\ j) = x << j$
  unfolding *shiftl-def* **apply** (*induction j*)
   apply *simp* **unfolding** *funpow-Suc-right*
  by (*metis* (*no-types, opaque-lifting*) *push-bit-eq-mult*)

lemma $(x::('a::len)\ word) * ((2\ \hat{}\ j)\ +\ 1) = x << j + x$
  by (*simp add: distrib-left*)

lemma $(x::('a::len)\ word) * ((2\ \hat{}\ j)\ -\ 1) = x << j - x$
  by (*simp add: right-diff-distrib*)

lemma $(x::('a::len)\ word) * ((2\hat{}j)\ +\ (2\hat{}k)) = x << j + x << k$
  by (*simp add: distrib-left*)

lemma $(x::('a::len)\ word) * ((2\hat{}j)\ -\ (2\hat{}k)) = x << j - x << k$
  by (*simp add: right-diff-distrib*)

definition *shiftr* (**infix** $>>>$ *75*) **where**
  shiftr w n = (drop-bit n) w

value $(255 :: 8\ word) >>> (2 :: nat)$

definition *sshiftr* :: $'a :: len\ word \Rightarrow nat \Rightarrow 'a :: len\ word$ (**infix** $>>$ *75*) **where**
  sshiftr w n = word-of-int $((sint\ w)\ div\ (2\ \hat{}\ n))$

value $(128 :: 8\ word) >> 2$

Note that Java shift operators use unary numeric promotion, unlike other
binary operators, which use binary numeric promotion (see the Java lan-
guage reference manual). This means that the left-hand input determines
the output size, while the right-hand input can be any size.

fun *shift-amount* :: $iwidth \Rightarrow int64 \Rightarrow nat$ **where**
  shift-amount b val = unat (*val AND* (*if b = 64 then 0x3F else 0x1f*))

fun *intval-left-shift* :: $Value \Rightarrow Value \Rightarrow Value$ **where**
  intval-left-shift (*IntVal b1 v1*) (*IntVal b2 v2*) = *new-int b1* (*v1* $<<$ *shift-amount
b1 v2*) |
  intval-left-shift - - = UndefVal

Signed shift is more complex, because we sometimes have to insert 1 bits at the correct point, which is at b1 bits.

fun *intval-right-shift* :: *Value* ⇒ *Value* ⇒ *Value* **where**
  intval-right-shift (*IntVal b1 v1*) (*IntVal b2 v2*) =
    (*let shift* = *shift-amount b1 v2 in*
    let ones = *mask b1 AND* (*NOT* (*mask* (*b1* − *shift*) :: *int64*)) *in*
    (*if int-signed-value b1 v1* < *0*
     then new-int b1 (*ones OR* (*v1* >>> *shift*))
     else new-int b1 (*v1* >>> *shift*))) |
  intval-right-shift - - = *UndefVal*

fun *intval-uright-shift* :: *Value* ⇒ *Value* ⇒ *Value* **where**
  intval-uright-shift (*IntVal b1 v1*) (*IntVal b2 v2*) = *new-int b1* (*v1* >>> *shift-amount b1 v2*) |
  intval-uright-shift - - = *UndefVal*

end

4 Nodes

4.1 Types of Nodes

theory *IRNodes*
  imports
    Values
begin

The GraalVM IR is represented using a graph data structure. Here we define the nodes that are contained within the graph. Each node represents a Node subclass in the GraalVM compiler, the node classes have annotated fields to indicate input and successor edges.

We represent these classes with each IRNode constructor explicitly labelling a reference to the node IDs that it stores as inputs and successors.

The inputs_of and successors_of functions partition those labelled references into input edges and successor edges of a node.

To identify each Node, we use a simple natural number index. Zero is always the start node in a graph. For human readability, within nodes we write INPUT (or special case thereof) instead of ID for input edges, and SUCC instead of ID for control-flow successor edges. Optional edges are handled as "INPUT option" etc.

4.2   Hierarchy of Nodes

theory *IRNodeHierarchy*
imports *IRNodes*
begin

It is helpful to introduce a node hierarchy into our formalization. Often the
GraalVM compiler relies on explicit type checks to determine which operations to perform on a given node, we try to mimic the same functionality
by using a suite of predicate functions over the IRNode class to determine
inheritance.

As one would expect, the function is<ClassName>Type will be true if the
node parameter is a subclass of the ClassName within the GraalVM compiler.

These functions have been automatically generated from the compiler.

5 Stamp Typing

theory *Stamp*
  imports *Values*
begin

The GraalVM compiler uses the Stamp class to store range and type information for a given node in the IR graph. We model the Stamp class as a datatype, Stamp, and provide a number of functions on the datatype which correspond to the class methods within the compiler.

Stamp information is used in a variety of ways in optimizations, and so, we additionally provide a number of lemmas which help to prove future optimizations.

datatype *Stamp =*
  VoidStamp
  | IntegerStamp (*stp-bits*: *nat*) (*stpi-lower*: *int*) (*stpi-upper*: *int*)

  | KlassPointerStamp (*stp-nonNull*: *bool*) (*stp-alwaysNull*: *bool*)
  | MethodCountersPointerStamp (*stp-nonNull*: *bool*) (*stp-alwaysNull*: *bool*)
  | MethodPointersStamp (*stp-nonNull*: *bool*) (*stp-alwaysNull*: *bool*)
  | ObjectStamp (*stp-type*: *string*) (*stp-exactType*: *bool*) (*stp-nonNull*: *bool*) (*stp-alwaysNull*: *bool*)
  | RawPointerStamp (*stp-nonNull*: *bool*) (*stp-alwaysNull*: *bool*)
  | IllegalStamp

fun *is-stamp-empty* :: *Stamp ⇒ bool* **where**
  is-stamp-empty (*IntegerStamp b lower upper*) = (*upper < lower*) |

  is-stamp-empty x = False

Just like the IntegerStamp class, we need to know that our lo/hi bounds fit into the given number of bits (either signed or unsigned). Our integer stamps have infinite lo/hi bounds, so if the lower bound is non-negative, we can assume that all values are positive, and the integer bits of a related value can be interpreted as unsigned. This is similar (but slightly more general) to what IntegerStamp.java does with its test: if (sameSignBounds()) in the unsignedUpperBound() method.

Note that this is a bit different and more accurate than what StampFactory.forUnsignedInteger does (it widens large unsigned ranges to the max signed range to allow all bit patterns) because its lo/hi values are only 64-bit.

fun *valid-stamp* :: *Stamp ⇒ bool* **where**
  valid-stamp (*IntegerStamp bits lo hi*) =
    (*0 < bits ∧ bits ≤ 64 ∧*
    fst (*bit-bounds bits*) ≤ *lo ∧ lo ≤ snd* (*bit-bounds bits*) *∧*
    fst (*bit-bounds bits*) ≤ *hi ∧ hi ≤ snd* (*bit-bounds bits*)) |

    HOL.Relation
begin

This theory defines the main Graal data structure - an entire IR Graph.

IRGraph is defined as a partial map with a finite domain. The finite domain is required to be able to generate code and produce an interpreter.

6.1 Control-flow Graph Traversal

theory
  Traversal
imports
  IRGraph
begin

type-synonym *Seen = ID set*

nextEdge helps determine which node to traverse next by returning the first successor edge that isn't in the set of already visited nodes. If there is not an appropriate successor, None is returned instead.

fun *nextEdge* :: *Seen* $\Rightarrow$ *ID* $\Rightarrow$ *IRGraph* $\Rightarrow$ *ID option* **where**
  nextEdge seen nid g =
    (*let nids = (filter* (λ*nid'. nid'* $\notin$ *seen*) (*successors-of* (*kind g nid*))) *in*
    (*if length nids > 0 then Some* (*hd nids*) *else None*))

pred determines which node, if any, acts as the predecessor of another.

Merge nodes represent a special case where-in the predecessor exists as an input edge of the merge node, to simplify the traversal we treat only the first input end node as the predecessor, ignoring that multiple nodes may act as a successor.

For all other nodes, the predecessor is the first element of the predecessors set. Note that in a well-formed graph there should only be one element in the predecessor set.

fun *pred :: IRGraph ⇒ ID ⇒ ID option* **where**
  pred g nid = (case kind g nid of
    (MergeNode ends - -) ⇒ Some (hd ends) |
    - ⇒
      (if IRGraph.predecessors g nid = {}
        then None else
        Some (hd (sorted-list-of-set (IRGraph.predecessors g nid)))
)
)

Here we try to implement a generic fork of the control-flow traversal algorithm that was initially implemented for the ConditionalElimination phase
